Security of IT infrastructure (2015/16)

# Content

Network access control

802.1X

EAP

RADIUS

Summary

# Network access control

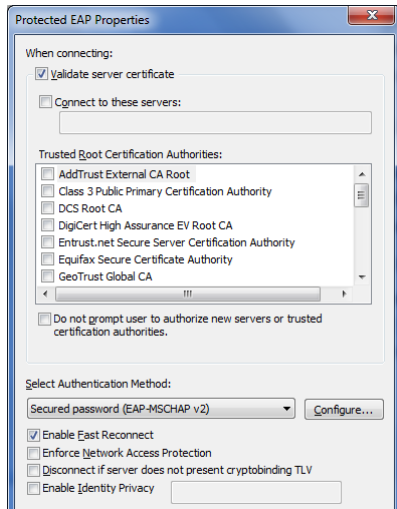

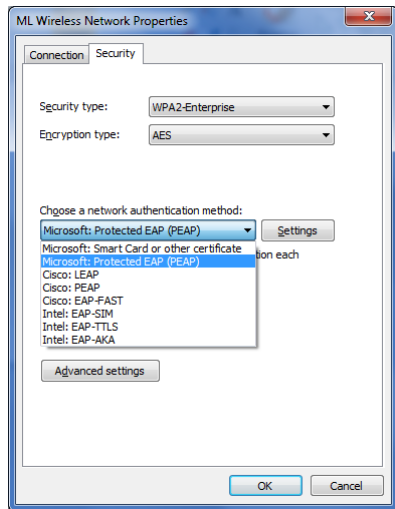

- ▶ AAA services ~ authentication, authorization, accounting
- ▶ **authentication**: verification (proving) of subject's identity
- ▶ authorization: determining whether the subject can perform given action
- ▶ accounting: tracking the use (consumption) of network resources
  - ▶ session duration, packets and data transferred, ...

# IEEE Std 802.1X

- ▶ Port-Based Network Access Control
- ▶ IEEE standard (versions 2001, 2004, 2010)
  - ▶ <http://standards.ieee.org/about/get/802/802.1.html>, more than 200 pages
- ▶ the standard:
  - ▶ specifies a general method for provision of port-based network access control;
  - ▶ specifies protocols that establish secure associations for IEEE Std 802.1AE MAC Security;  
(MAC – Media Access Control, part of a link layer in OSI model),  
encryption and integrity for Layer 2 (default AES-128-GCM)
  - ▶ facilitates the use of industry standard authentication and authorization protocols.
- ▶ example: WPA2 Enterprise (WPA2-802.1X, Wi-Fi Protected Access II)
  - ▶ cf. WPA2 Personal (WPA2-PSK, Pre-shared key)

# Windows 7

- WiFi; Wired AutoConfig service for 802.1X on wired Ethernet interfaces

# Ubuntu 15.10 (Wired connection)

## ► NetworkManager

Editing Wired connection 1

Connection name: Wired connection 1

General Ethernet 802.1X Security DCB IPv4 Settings IPv6 Settings

☒ Use 802.1X security for this connection

Authentication: Protected EAP (PEAP)

Anonymous identity:

CA certificate: (None)

☐ No CA certificate is required

PEAP version: Automatic

Inner authentication: MSCHAPv2

# Subjects and roles in 802.1X

- ▶ **Supplicant (client)**
  - ▶ SW, e.g. part of an operating system
  - ▶ HW, e.g. Intel AMT (part of Intel vPro platform)
- ▶ **Authenticator** – facilitates authentication of other entities
- ▶ **Authentication server** – provides an authentication service

# What's going on in 802.1X

- ▶ initial state: port (access point) is closed for any client's communication except EAPoL (EAP over LAN)
- ▶ client (supplicant) performs authentication against authentication server (EAP, Extensible Authentication Protocol)
  - ▶ success: authenticator opens port, assigns VLAN etc.
  - ▶ failure: authenticator keeps port closed / opens port and assigns the client to guest VLAN etc.

# Protocols in 802.1X

- ▶ EAPoL (EAP over LAN)
  - ▶ facilitates communication supplicant ↔ authenticator
  - ▶ runs over 802.3 (Ethernet), 802.11 (WLAN), ...
  - ▶ packs EAP messages into L2 communication
- ▶ RADIUS ... details later
  - ▶ communication authenticator ↔ authentication server
  - ▶ in this scenario: EAP messages packed into messages of RADIUS protocol

# Challenges for deployment

- ▶ some EAP methods need certificates – certificate management (provisioning), both server's and supplicant's certificates
- ▶ network devices without 802.1X support (e.g. printers)
- ▶ Wake on LAN
- ▶ multiple devices on single network port (IP phones, hub etc.)
- ▶ unavailable authentication server

...etc. ...

# EAP (Extensible Authentication Protocol)

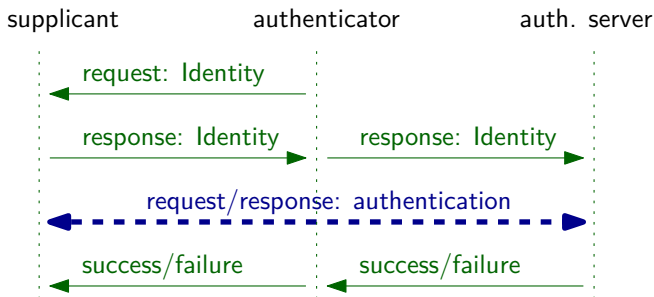

- ▶ originally an extension of PPP (Point-to-point protocol), now RFC 3748
- ▶ typically over data link layer (e.g. PPP, IEEE 802; i.e. without IP)
- ▶ general authentication framework for multiple authentication methods
- ▶ packet format:

- ▶ identifier aids in matching responses with corresponding requests
- ▶ RFC 5296: new codes introduced (5 Initiate, 6 Finish)

## EAP (2)

- ▶ very simple protocol
  - ▶ (potentially) large number of request/response messages, usually finished with success/failure
- ▶ example:

## EAP (3)

- complexity in authentication methods

1/2	identifier	length (2B)
type	data for particular auth. method	

- examples of authentication methods (more than 40, optional custom extensions):

4	MD5	21	PEAP
13	TLS	43	FAST
21	TTLS	49	IKEv2

# EAP-MD5

- ▶ mandatory method (standard-compliant implementation must support)
- ▶ implementation CHAP (Challenge Handshake Authentication Protocol):
  - ▶ Request: *challenge*
  - ▶ Response: MD5(identifier || *shared secret* || *challenge*)
- ▶ **avoid** this method – security problems:
  - ▶ only one-sided (client/supplicant) authentication
  - ▶ vulnerable to dictionary and brute-force attacks
  - ▶ vulnerable to MITM attack ... messages in clear-text without any protection of integrity/authenticity
  - ▶ identity of client revealed
  - ▶ no support for cryptographic key generation – cannot protect further communication
  - ▶ ...

# EAP-TLS, EAP-TTLS and EAP-PEAP

Ideas (outer EAP used mostly for solving packet fragmentation):

- ▶ EAP-TLS: using TLS authentication
- ▶ EAP-TTLS: client authentication (as AVP) tunneled in TLS
- ▶ EAP-PEAP: inner EAP instance tunneled in TLS

	EAP-TLS	EAP-TTLS	EAP-PEAP
client certificate	yes	optional	optional
server certificate	yes	yes	yes
mutual authentication	yes	yes	yes
key generation	yes	yes	yes
identity protection of client	no	yes	yes

## Some inner authentication methods

- ▶ CHAP ...with MD5 was discussed before
- ▶ MS-CHAPv2 ...CHAP variant (defined in RFC 2759)
  - ▶ mutual (two-way) authentication
  - ▶ free from LAN Manager history
  - ▶ generating cryptographic keys
  - ▶ frequently used in practice
  - ▶ interesting analysis (standalone MS-CHAPv2):  
Divide and Conquer: Cracking MS-CHAPv2 with a 100% success rate (2012)  
[www.cloudcracker.com/blog/2012/07/29/cracking-ms-chap-v2/](http://www.cloudcracker.com/blog/2012/07/29/cracking-ms-chap-v2/)

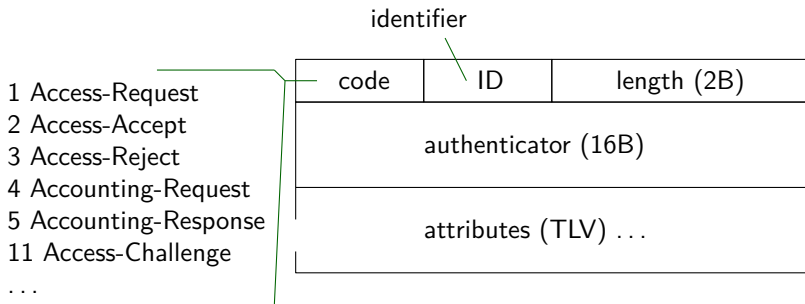

# RADIUS

- ▶ RADIUS – Remote Authentication Dial In User Service
- ▶ RFC 2865, RFC 2866 (Accounting) + other extensions
- ▶ centralized authentication of users and systems
- ▶ AAA services
- ▶ client/server protocol
  - ▶ client (NAS – Network Access Server):  
switch, router, access point, VPN server ...
  - ▶ server (RADIUS server):  
FreeRADIUS, Network Policy Server (Microsoft), Secure Access Control Server (Cisco)

# Basic characteristics

- ▶ stateless protocol (UDP)
- ▶ database of users: SQL database, LDAP, text files, ...
- ▶ communication client ↔ server (initialized by client)
- ▶ proxy RADIUS server (facilitates roaming of users between realms)

# Packet

## ► authenticator:

- request auth. (in Access-Request packets) – unpredictable and unique over lifetime of a secret
- response auth. (Access-[Accept, Reject, Challenge] packets)  
MD5(code || ID || length || request auth. || attributes || secret)
- secret – password shared by client and server

# Security (1)

- ▶ user password (P) is transmitted encrypted
  - ▶ password padded with 0x00 to multiple of 16 B
  - ▶ encryption:  $P \oplus \text{MD5}(\text{secret} \parallel \text{request auth.})$
  - ▶ other attributes in clear-text (security?, privacy?)
- ▶ value *secret*
  - ▶ dictionary attack or brute-force attack (using response auth. or encrypted password)
  - ▶ often the same values used in multiple NAS  $\Rightarrow$  fake NAS, attacking user passwords

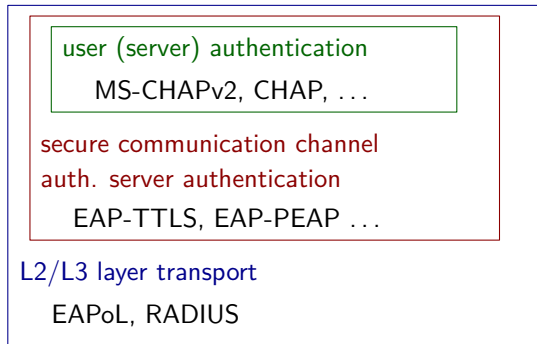

## Security (2)

- ▶ vulnerability – repeating or predictability of request auth.
  - ▶ get server's responses in advance and repeat them later (see also Event-Timestamp attribute)
- ▶ Access-Request without integrity protection
  - ▶ see Message-Authenticator attribute (HMAC-MD5 for entire packet, key is *secret*)
- ▶ some risks are mitigated by employing suitable EAP method
- ▶ protection of the protocol – providing secure channel
  - ▶ IPSec, RadSec – RADIUS over TLS
- ▶ RADIUS support for EAP (RFC 3579)

# Alternatives and improvements

- ▶ TACACS+ (Terminal Access Controller Access-Control System)
  - ▶ proprietary Cisco protocol, primary for access to network components
  - ▶ over TCP, separation of authentication and authorization
  - ▶ (optional) encrypted body of the packet (without header)
- ▶ DIAMETER
  - ▶ intended replacement for RADIUS (slow adoption)
  - ▶ basics defined in RFC 3588
  - ▶ over reliable transport layer (TCP, SCTP)
  - ▶ over secure communication channel (IPSec, TLS)
  - ▶ both stateful and stateless models
  - ▶ easy to extend, ...

## Summary – architecture (802.1X example)

# Summary – messages (802.1X example)
